Research highlights

► The probability of a subject aged 60–64 living in Madrid of being vaccinated was almost two times higher (OR 1.95 CI 95% 1.46–2.61) than a person of the same age who lived in a region of Spain where the universal recommendation for influenza vaccine started at 65 years. ► Lowering the age for universal influenza vaccination should be considered as a strategy to increase coverages among high risk patients who suffer from chronic underlying conditions.

Efficacy of hepatitis B sero-vaccination in newborns of African HBsAg positive mothers
